#### INTRODUCTION

The KS0713 is a driver & controller LSI for graphic dot-matrix liquid crystal display systems. It contains 65 commons and 132 segments driver circuits. This chip is connected directly to a microprocessor, accepts serial or 8-bit parallel display data and stores in an on-chip Display Data RAM of 65 x 132 bits. It provides a high-flexible display section due to 1-to-1 correspondence between on-chip display data RAM bits and LCD panel pixels. And it performs display data RAM read/write operation with no externally operating clock to minimize power consumption. In addition, because it contains power supply circuits necessary to drive liquid crystal, it is possible to make a display system with the fewest components.

#### **FEATURES**

#### **Driver Output Circuits**

65 common outputs / 132 segment outputs

#### **On-chip Display Data RAM**

- Capacity:  $65 \times 132 = 8,580$  bits

#### **Applicable Duty Ratios**

Duty ratio	Applicable LCD bias	Maximum display area
1/65	1/7 or 1/9	65 × 132
1/49	1/6 or 1/8	49 × 132
1/33	1/5 or 1/6	33 × 132

#### **Microprocessor Interface**

- 8-bit parallel bi-directional interface with 6800-series or 8080-series
- Serial interface (only write operation) available

#### **Function Set**

- Various instructions sets
- H/W, S/W reset capable

#### **Built-in Analog Circuit**

- On-chip oscillator circuit
- Voltage converter (x2, x3, x4, x5)
- Voltage regulator (temperature coefficient: -0.05%/°C, -0.2%/°C)
- Voltage follower
- Electronic contrast control function (64 steps)

#### **Operating Voltage Range**

- Supply voltage (VDD): 2.4 to 3.6 V
- LCD driving voltage (VLCD = V0 VSS): 4.0 to 15.0 V

#### **Low Power Consumption**

- 70 μA Typ. (VDD = 3V, x4 boosting, V0 = 11V, internal power supply ON)
- 10 μA Max. (during power save [standby] mode)

#### **FUNCTIONAL DESCRIPTION**

#### **MICROPROCESSOR INTERFACE**

#### **Chip Select Input**

There are CS1B and CS2 pins for Chip Selection. The KS0713 can interface with an MPU only when CS1B is "L" and CS2 is "H". When these pins are set to any other combination, RS, E\_RD, and RW\_WR inputs are disabled and DB0 to DB7 are to be high impedance. And, in case of serial interface, the internal shift register and the counter are reset.

#### Parallel / Serial Interface

KS0713 has three types of interface with an MPU, which are one serial and two parallel interfaces. This parallel or serial interface is determined by PS pin as shown in table 8.

Table 8. Parallel / Serial Interface Mode

PS	Туре	CS1B	CS2	MI	Interface mode
1.1	Dorollol	CCAD	663	Н	6800-series MPU mode
H	Parallel	CS1B	CS2	L	8080-series MPU mode
L	Serial	CS1B	CS2	*×	Serial-mode

\*x: Don't care

#### Parallel Interface (PS = "H")

The 8-bit bi-directional data bus is used in parallel interface and the type of MPU is selected by MI as shown in table 9. The type of data transfer is determined by signals at RS, E\_RD and RW\_WR as shown in table10.

**Table 9. Microprocessor Selection for Parallel Interface** 

MI	CS1B	CS2	RS	E_RD	RW_WR	DB0 to DB7	MPU bus
Н	CS1B	CS2	RS	E	RW	DB0 to DB7	6800-series
L	CS1B	CS2	RS	/RD	/WR	DB0 to DB7	8080-series

**Table 10. Parallel Data Transfer** 

Common	6800-	series	8080-	series	Description	
RS	E_RD (E)	RW_WR (RW)	E_RD (/RD)	RW_WR (/WR)		
Н	Н	Н	L	Н	Display data read out	
Н	Н	L	Н	L	Display data write	
L	Н	Н	L	Н	Register status read	
L	Н	L	Н	L	Writes to internal register (instruction)	

#### Serial Interface (PS = "L")

When the KS0713 is active, serial data (DB7) and serial clock (DB6) inputs are enabled. And not active, the internal 8-bit shift register and the 3-bit counter are reset. Serial data can be read on the rising edge of serial clock going into DB6 and processed as 8-bit parallel data on the eighth serial clock. Serial data input is display data when RS is high and control data when RS is low. Since the clock signal (DB6) is easy to be affected by the external noise caused by the line length, the operation check on the actual machine is recommended.

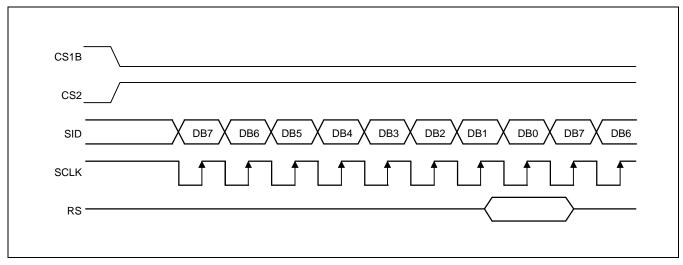

Figure 3. Serial Interface Timing

#### **Busy Flag**

The Busy Flag indicates whether the KS0713 is operating or not. When DB7 is "H" in read status operation, this device is in busy status and will accept only read status instruction. If the cycle time is correct, the microprocessor needs not to check this flag before each instruction, which improves the MPU performance.

#### **Data Transfer**

The KS0713 uses bus holder and internal data bus for Data Transfer with the MPU. When writing data from the MPU to on-chip RAM, data is automatically transferred from the bus holder to the RAM as shown in figure 4. And when reading data from on-chip RAM to the MPU, the data for the initial read cycle is stored in the bus holder (dummy read) and the MPU reads this stored data from bus holder for the next data read cycle as shown in figure 5. This means that a dummy read cycle must be inserted between each pair of address sets when a sequence of address sets is executed. Therefore, the data of the specified address cannot be output with the read display data instruction right after the address sets, but can be output at the second read of data.

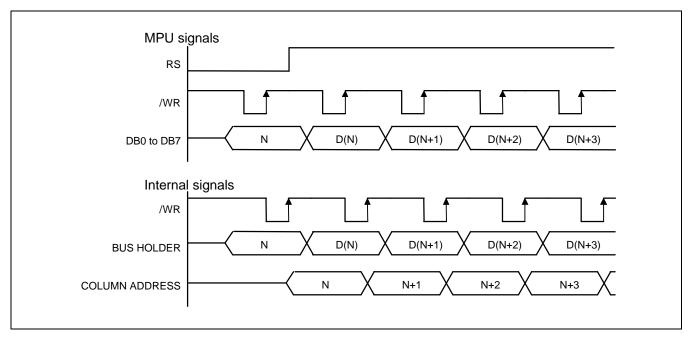

Figure 4. Write Timing

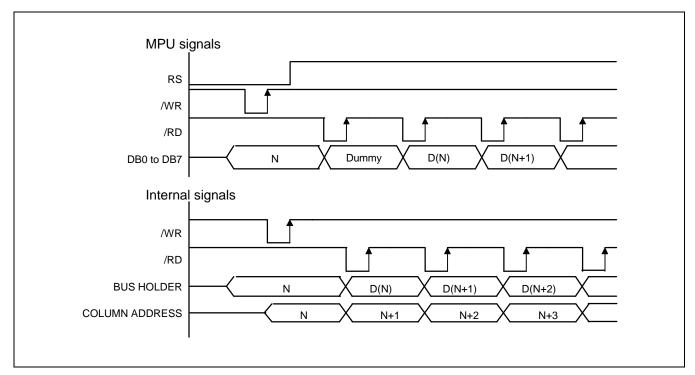

Figure 5. Read Timing

#### **DISPLAY DATA RAM (DDRAM)**

The Display Data RAM stores pixel data for the LCD. It is 65-row by 132-column addressable array. Each pixel can be selected when the page and column addresses are specified. The 65 rows are divided into 8 pages of 8 lines and the 9th page with a single line (DB0 only). Data is read from or written to the 8 lines of each page directly through DB0 to DB7. The display data of DB0 to DB7 from the microprocessor correspond to the LCD common lines as shown in Figure 6. The microprocessor can read from and write to RAM through the I/O buffer. Since the LCD controller operates independently, data can be written into RAM at the same time as data is being displayed without causing the LCD flicker.

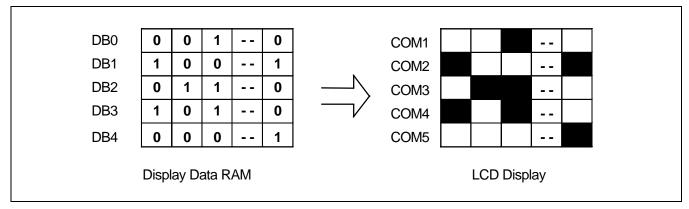

Figure 6. RAM-to-LCD Data Transfer

#### **Page Address Circuit**

This circuit is for providing a Page Address to Display Data RAM shown in figure 8. It incorporates 4-bit Page Address register changed by only the "Set Page" instruction. Page Address 8 (DB3 is "H", but DB2, DB1 and DB0 are "L") is a special RAM area for the icons and display data DB0 is only valid. When Page Address is above 8, it is impossible to access to on-chip RAM.

#### **Line Address Circuit**

This circuit assigns DDRAM a Line Address corresponding to the first line (COM1) of the display. Therefore, by setting line address repeatedly, it is possible to realize the screen scrolling and page switching without changing the contents of on-chip RAM as shown in figure 8. It incorporates 6-bit line address register changed by only the initial display line instruction and 6-bit counter circuit. At the beginning of each LCD frame, the contents of register are copied to the line counter which is increased by CL signal and generates the Line Address for transferring the 132-bit RAM data to the display data latch circuit. However, display data of icons are not scrolled because the MPU can not access Line Address of icons.

#### Column Address Circuit

Column address circuit has a 8-bit preset counter that provides column address to the Display Data RAM as shown in figure 8. When set Column Address MSB / LSB instruction is issued, 8-bit [Y7:Y0] is updated. And, since this address is increased by 1 each a Read or Write Data instruction, microprocessor can access the display data continuously. However, the counter is not increased and locked if a non-existing address above 84H. It is unlocked if a column address is set again by set Column Address MSB / LSB instruction. And the Column Address counter is independent of page address register.

ADC select instruction makes it possible to invert the relationship between the Column Address and the segment outputs. It is necessary to rewrite the display data on built-in RAM after issuing ADC select instruction. Refer to the following figure 7.

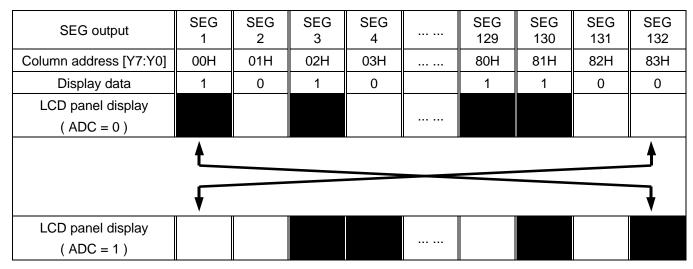

Figure 7. The Relationship between the Column Address and the Segment Outputs

#### **Segment Control Circuit**

This circuit controls the display data by the Display ON / OFF, Reverse display ON / OFF and entire display ON / OFF instructions without changing the data in the display data RAM.

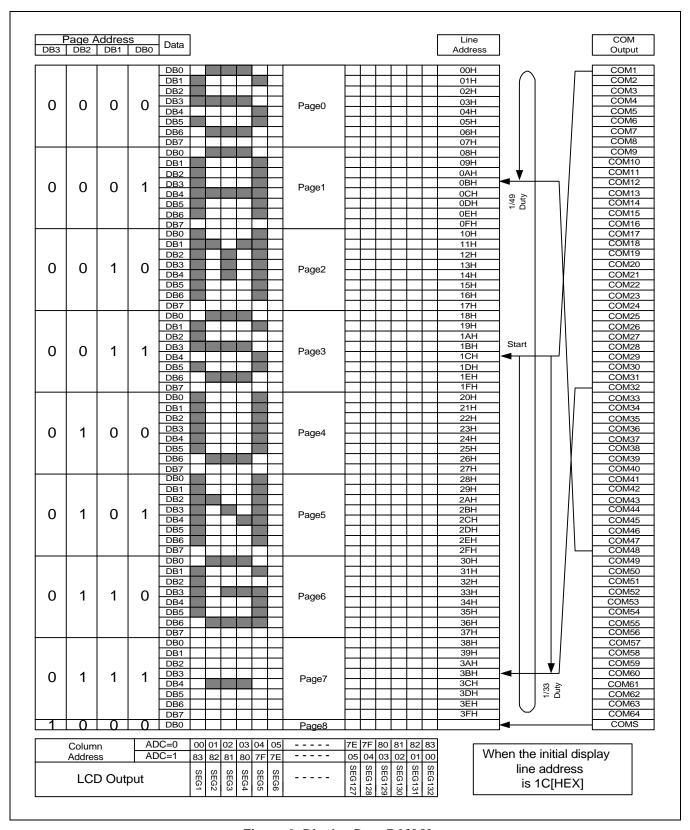

Figure 8. Display Data RAM Map

#### LCD DISPLAY CIRCUITS

#### Oscillator

This is completely on-chip oscillator and its frequency is nearly independent of VDD. This oscillator signal is used in the voltage converter and display timing generation circuit.

\* Test condition: Temperature: 25°C & 85°C, TEMPS="L", No load

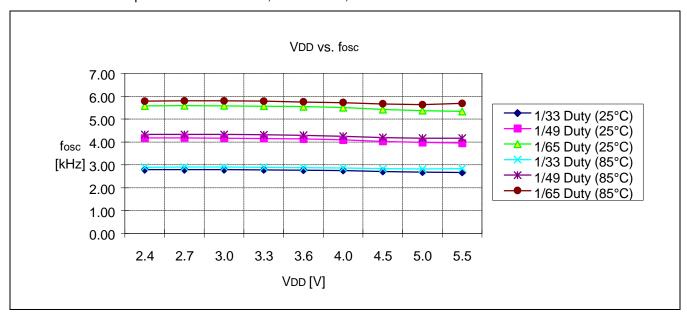

Figure 9. VDD vs. fosc

#### **Display Timing Generator Circuit**

This circuit generates some signals to be used for displaying LCD. The display clock, CL, generated by oscillation clock, generates the clock for the line counter and the signal for the display data latch. The line address of on-chip RAM is generated in synchronization with the display clock (CL) and the 132-bit display data is latched by the display data latch circuit in synchronization with the display clock. The display data, which is read to the LCD driver, is completely independent of the access to the display data RAM from the microprocessor. The display clock generates an LCD AC signal (M) which enables the LCD driver to make a AC drive waveform, and also generates an internal common timing signal and start signal to the common driver. Driving 2-frame AC driver waveform and internal timing signal are shown in figure 9.

In a multiple-chip configuration, the slave chip requires the M, CL and DISP signals from the master. Table 11 shows the M, CL, and DISP status.

Operation mode	Oscillator	М	CL	DISP
Mootor	ON (internal clock used)	Output	Output	Output
Master	OFF (external clock used)	Output	Input	Output
Slave	-	Input	Input	Input

#### **Common Output Control Circuit**

This circuit controls the relationship between the number of common output and specified duty ratio. SHL Select Instruction specifies the scanning direction of the common output pins.

#### **LCD DRIVER CIRCUIT**

This driver circuit is configured by 66-channel common drivers (including 2 COMS channels) and 132-channel segment drivers. This LCD panel driver voltage depends on the combination of display data and M signal.

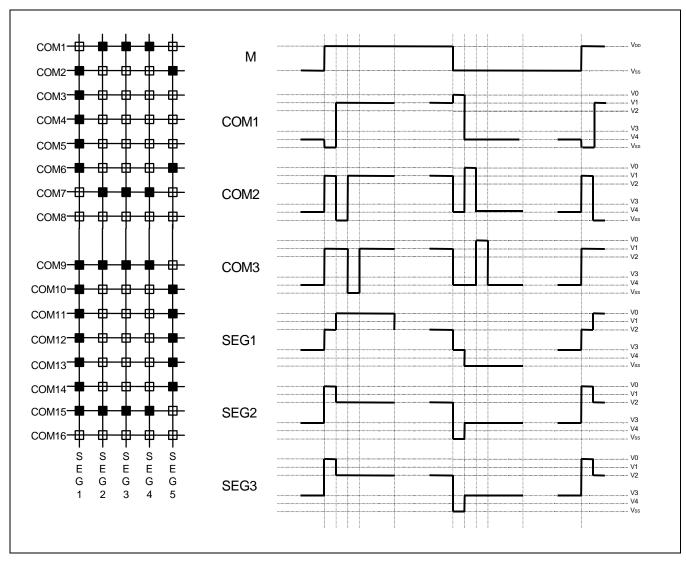

Figure 11. Segment and Common Timing

#### **POWER SUPPLY CIRCUITS**

The Power Supply circuits generate the voltage levels necessary to drive liquid crystal driver circuits with low power consumption and the fewest components. There are voltage converter circuits, voltage regulator circuits, and voltage follower circuits. They are valid only in master operation and controlled by power control instruction. For details, refers to "Instruction Description". Table 13 shows the referenced combinations in using power supply circuits.

**Table 13. Recommended Power Supply Combinations**

#### **Voltage Converter Circuits**

These circuits boost up the electric potential between VDD and VSS to 2, 3, 4 or 5 times toward positive side and boosted voltage is outputted from VOUT pin.

#### **Voltage Regulator Circuits**

The function of the internal Voltage Regulator circuits is to determine liquid crystal operating voltage, V0, by adjusting resistors, Ra and Rb, within the range of |V0| < |VOUT|. Because VOUT is the operating voltage of operational-amplifier circuits shown in figure 16, it is necessary to be applied internally or externally.

For the Eq. 1, we determine V0 by Ra, Rb and VEV. The Ra and Rb are connected internally or externally by INTRS pin. And VEV called the voltage of electronic volume is determined by Eq. 2, where the parameter  $\alpha$  is the value selected by instruction, "Set Reference Voltage Register", within the range 0 to 63. VREF voltage at Ta = 25°C is shown in table 14-1.

$$V0 = (1 + \frac{Rb}{Ra}) \times VEV [V] ----- (Eq. 1)$$

$$VeV = (1 - \frac{(63 - \alpha)}{300}) \times VeeF [V] ----- (Eq. 2)$$

Table 14-1. VREF Voltage at Ta = 25 °C

#### In Case of Using Internal Resistors, Ra and Rb (INTRS = "H")

When INTRS pin is "H", resistor Ra is connected internally between VR pin and Vss, and Rb is connected between V0 and VR. We determine V0 by two instructions, "Regulator Resistor Select" and "Set Reference Voltage".

		3-bit data settings (R2 R1 R0)								
	0 0 0	0 0 1	010	011	100	101	110	111		
1+(Rb / Ra)	1.90	2.19	2.55	3.02	3.61	4.35	5.29	6.48		

Table 15. Internal Rb / Ra Ratio depending on 3-bit Data (R2 R1 R0)

The following figure shows V0 voltage measured by adjusting internal regulator resistor ratio (Rb / Ra) and 6-bit electronic volume registers for each temperature coefficient at Ta = 25 °C.

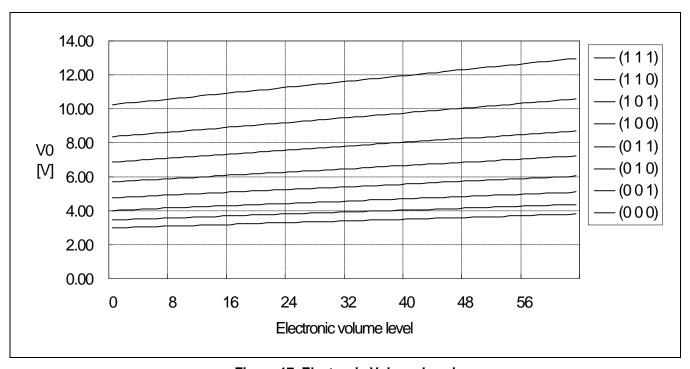

Figure 17. Electronic Volume Level

#### In Case of Using External Resistors, Ra and Rb. (INTRS = "L")

When INTRS pin is "L", it is necessary to connect external regulator resistor Ra between VR and Vss, and Rb between V0 and VR.

Example: For the following requirements

- 1. LCD driver voltage, V0 = 10V
- 2. 6-bit reference voltage register = (1, 0, 0, 0, 0, 0)
- 3. Maximum current flowing Ra, Rb = 1 uA

From Eq. 2 
$$(63 - 32)$$
 VEV =  $(1 - \frac{(63 - 32)}{300})$  x 2.0 = 1.79 [V] ----- (Eq. 4)

From requirement 3.

From equations Eq. 3, 4 and 5

Ra = 1.79 [M $\Omega$ ]

Rb = 8.21 [M $\Omega$ ]

The following table shows the range of V0 depending on the above requirements.

Table 16. V0 Depending on Electronic Volume Level

	Electronic volume level							
	0		32		63			
V0	8.83		10.00		11.17			

#### **Voltage Follower Circuits**

VLCD voltage (V0) is resistively divided into four voltage levels (V1, V2, V3 and V4) and those output impedance are converted by the Voltage Follower for increasing drive capability. The following table shows the relationship between V1 to V4 level and each duty ratio.

Table 17. The Relationship between V1 to V4 level and Duty Ratio

#### RESET CIRCUIT

Setting RESETB to "L" or Reset instruction can initialize internal function. When RESETB becomes "L", following procedure is occurred.

Display ON / OFF: OFF

Entire display ON / OFF: OFF (normal)

ADC select: OFF (normal)

Reverse display ON / OFF: OFF (normal) Power control register (VC, VR, VF) = (0, 0, 0)

LCD bias ratio: 1/7 (1/65 duty), 1/6 (1/49 duty), 1/5 (1/33 duty)

Read-modify-write: OFF SHL select: OFF (normal) Static indicator mode: OFF

Static indicator register: (S1, S0) = (0, 0)

Display start line: 0 (first) Column address: 0 Page address: 0

Regulator resistor select register: (R2, R1, R0) = (0, 0, 0)

Reference voltage set: OFF

Reference voltage control register: (SV5, SV4, SV3, SV2, SV1, SV0) = (1, 0, 0, 0, 0, 0)

When RESET instruction is issued, following procedure is occurred.

Read-modify-write: OFF Static indicator mode: OFF

Static indicator register: (S1, S0) = (0, 0)

SHL select: 0

Display start line: 0 (first) Column address: 0 Page address: 0

Regulator resistor select register: (R2, R1, R0) = (0, 0, 0)

Reference voltage set: OFF

Reference voltage control register: (SV5, SV4, SV3, SV2, SV1, SV0) = (1, 0, 0, 0, 0, 0)

While RESETB is "L" or Reset instruction is executed, no instruction except read status can be accepted. Reset status appears at DB4. After DB4 becomes "L", any instruction can be accepted. RESETB must be connected to the reset pin of the MPU, and initialize the MPU and this LSI at the same time. The initialization by RESETB is essential before used.

### **Read Display Data**

8-bit data from Display Data RAM specified by the column address and page address can be read by this instruction. As the column address is increased by 1 automatically after each this instruction, the microprocessor can continuously read data from the addressed page. A dummy read is required after loading an address into the column address register. Display Data cannot be read through the serial interface.

### **Set Page Address**

Sets the Page Address of display data RAM from the microprocessor into the Page Address register. Any RAM data bit can be accessed when its Page Address and column address are specified. Along with the column address, the Page Address defines the address of the display RAM to write or read display data. Changing the Page Address doesn't effect to the display status.

#### **Set Column Address**

Sets the Column Address of display RAM from the microprocessor into the Column Address register. Along with the Column Address, the Column Address defines the address of the display RAM to write or read display data. When the microprocessor reads or writes display data to or from display RAM, column addresses are automatically increased.

REV	RAM bit data = "1"	RAM bit data = "0"
0 (normal)	LCD pixel is illuminated	LCD pixel is not illuminated
1 (reverse)	LCD pixel is not illuminated	LCD pixel is illuminated

## **Entire Display ON / OFF**

Forces the whole LCD points to be turned on regardless of the contents of the display data RAM. At this time, the contents of the display data RAM are held. This instruction has priority over the reverse display ON / OFF instruction.

RS	RW	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0
0	0	1	0	1	0	0	1	0	EON

EON = 0: normal display

1/49	0	1	1/6 1/8	
1/65	1	0/1	1/7 1/9	

## **Set Modify-Read**

This instruction stops the automatic increment of the column address by the read display data instruction, but the column address is still increased by the write display data instruction. And it reduces the load of microprocessor when the data of a specific area is repeatedly changed during cursor blinking or others. This mode is canceled by the reset Modify-read instruction.

RS	RW	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0
0	0	1	1	1	0	0	0	0	0

## **Reset Modify-Read**

This instruction cancels the Modify-read mode, and makes the column address return to its initial value just before the set Modify-read instruction is started.

#### **Set Static Indicator State**

Consists of two bytes instruction. The first byte instruction (set Static Indicator mode) enables the second byte instruction (set Static Indicator register) to be valid. The first byte sets the static indicator ON / OFF. When it is on, the second byte updates the contents of static indicator register without issuing any other instruction and this static indicator state is released after setting the data of indicator register.

1	1	ON (always ON)

### **Power Save (Compound Instruction)**

If the entire display ON / OFF instruction is issued during the display OFF state, KS0713 enters the Power Save status to reduce the power consumption to the static power consumption value. According to the status of static indicator mode, power save is entered to one of two modes (sleep and standby mode). When static indicator mode is ON, standby mode is issued, when OFF, sleep mode is issued. Power Save mode is released by the display ON and entire display OFF instruction.

### [\* Remark Solves]

- \*1. Though the wide range of operating voltages is guaranteed, a spike voltage change may affect the voltage assurance during access from the MPU.
- \*2. In case of external power supply is applied.
- \*3. CS1B, CS2, RS, DB0 to DB7, E\_RD, RW\_WR, RESETB, MS, MI, PS, INTRS, HPM, TEMPS, BSTS, DCDC5B, CLS, CL, M, DISP pins.
- \*4. DB0 to DB7, M, FRS, DISP, CL pins.
- \*5. CS1B, CS2, RS, DB [7:0], E\_RD, RW\_WR, RESETB, MS, MI, PS, INTRS, HPM, TEMPS, BSTS, DCDC5B, CLS, CL, M, DISP pins.
- \*6. Applies when the DB [7:0], M, DISP, and CL pins are in high impedance.
- \*7. Resistance value when  $\pm$  0.1[mA] is applied during the ON status of the output pin SEGn or COMn. RON=  $\Delta V$  / 0.1 [k $\Omega$ ] ( $\Delta V$ : voltage change when  $\pm$  0.1[mA] is applied in the ON status.)
- \*8. See table 21 for the relationship between oscillation frequency and frame frequency.
- \*9. The voltage regulator circuit adjusts V0 within the voltage follower operating voltage range
- \*10. On-chip reference voltage source of the voltage regulator circuit to adjust V0.
- \*11,12. Applies to the case where the on-chip oscillation circuit is used and no access is made from the MPU.

The current consumption, when the built-in power supply circuit is ON or OFF.

The current flowing through voltage regulation resistors (Ra and Rb) is not included.

It does not include the current of the LCD panel capacity, wiring capacity, etc.
